Name: | Student ID:

1. What type of variable is being measured by each of the following questions?

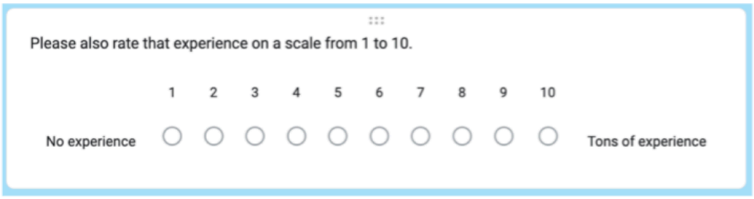

A

B

C

D

E

What zip code do you consider home? (If from abroad, use UC Berkeley's 94720)

2. Last class you collected data on six different variables on your classmates. List the data types of each of those variables, the units that they were measured in (if it's continuous numerical), and the range of possible values that you would expect them to take.

- Name:
- Contact info:
- Hometown:
- # Siblings:
- # Semesters in college:
- Farthest distance from campus during the break (assume it's in miles)

3. As discussed in the lecture notes, this is **not** a data frame:

		Alien color		
		Green	Blue	Total
Time of sighting	Night	55	11	66
	Day	23	55	78
	Total	78	66	144

But **where did this data came from?** Imagine you are researchers who are collecting this data, and you record your observations as rows in a dataframe.

- What would the *unit* of observation be?

- How many rows would there be? How many columns would there be?

- Sketch a schematic of the data frame based off of your answers to the above (just column names and a few example rows)

@. Pull out your worksheet from yesterday's class again! You'll now be storing some of the data you collected using R code.

- Note: if you haven't already, you really need to read today's tutorial (to learn to code) and watch the video about R Studio (so you know how to use our coding environment).
- Open R Studio, create a new Quarto document, and save it.
- Insert a new code cell.
- Create three vectors: `name`, `hometown`, and `sibs_and_pets` filled with your data.
- **You don't need to turn in the code file itself** - just copy down the code you wrote, once it's working.

- Combine the three vectors into a data frame called `my_classmates`. Copy the code you used below.
